

API Element

Definition

API Element is a type of plugin that exposes a set of functions to interact or exchange data with the Joget server.

It's as simple as a drag-and-drop into the builder canvas, with a straightforward simple UI to configure the plugin.

You can also create your own API Plugins to extend the API Builder's functionality.

See more here: [API Element Plugin](#)

The screenshot displays the API Builder interface for 'Expenses Claim v1: Expense Claim Data (Published)'. The interface is divided into four main sections: DESIGN, PROPERTIES, OAS3 DOCUMENT, and SAVE. The DESIGN section is active, showing a sidebar with various API elements like App, Form, List, Assignment, Audit Trail, Department, Grade, Group, Organization, User, Form Audit Trail, Process, SLA, SSO, and System. The main canvas shows the configuration for the 'Form' element, which includes a dropdown menu for 'Form *', a text input for 'Short Description', and four checkboxes: 'Add form data', 'Delete form data', 'Get form data by record ID', and 'Update form data'.
