## **Optimizing Joget Platform**

Here are some steps to troubleshoot and optimize your Joget platform:

- Important Articles:
  - O How to Solve Your Joget Enterprise App Performance Problems
  - O Joget Performance Optimization and Scalability Tips
  - O Joget Development Server Data Cleaning
- Environment:
  - O Check the JVM heap and permgen memory usage. Is the system out of memory? If so, it's likely there's a memory leak somewhere. You can use VisualVM to check on memory usage and do a heap dump if required. Tuning Tomcat Performance.
  - Perform a thread dump when the system is slow. This gives a snapshot of what is happening at a specific time so you can see what classes and methods are running. With this, you can identify what is hogging system resources. You can use VisualVM for this too.
  - O Check on system resources e.g. CPU, RAM, swap usage. Are they taken up by Java, the DB, or other processes?
  - O Narrow down the issue. Is it slow all the time for every request, or just for some specific requests? Is it slow immediately even after a restart, or over some time?
  - O Upgrade the server hardware with additional DRAM and increase your heap space allocation.
  - O Use the Performance Analyzer to identify which part in Userview taken a long time to process.
  - O Use the Application Performance Management to analyze.
- Programming & Database:
  - O Review your custom plugins/BeanShells to ensure all resources are properly closed and released.
  - O Are you running the database on a separate server from the Joget application server? Reference
  - O Do check the database slow logs for a clue to slow queries.
  - O Add an index to all your foreign keys in your database tables that are frequently accessed in datalist or JDBC. See https://dzone.com/articles/how-to-optimize-mysql-queries-for-speed-and-perfor
  - O Upgrade to the latest database version, as it will come with new security fixes and faster performance.
- App Design:
  - O Do consider placing the "daily use" & "setup/administration" menus into two separate userviews to make the datalist compact and fast. Add a link in each userview to jump from userview1 to userview2 and vice versa.
  - 9 Remove/hide all menu counts where possible. Menu counts in other datalist in the same userview affect performance as it needs to perform a count in other datalist too to populate the menus.
  - O Use Sync LDAP User Directory Manager to improve performance retrieving user information in your app.
  - O Use the free AJAX Select Box Plugin plugin from Joget Marketplace if you have options fields with large datasets
  - O Use Performance Improvement with Userview Caching
  - O Use Form Options Caching
  - O In your development or staging servers, delete unneeded or unused old versions of the app (that are unpublished). Just maintain 2 copies of the app, the current published version, and one older version.
  - O Read Datalist Performance Considerations
- Resource Heavy Plugins if the following plugins are not used for analysis at all, remove them for better performance:
  - O Form Data Audit Trail
    - O Process Data Collector
- GIT:
- Joget v7.0.6 and higher has an option in JAVA\_OPT parameter to disable or turn off the Git. This reduces the processing overhead on Joget, by adding -Dgit.disabled=true to your Joget startup script.
- O We do not recommend turning off GIT as you will lose the ability to track changes to the app itself. The benefits of having GIT for app change auditing/traceability outweigh the potential performance gain.
- Scale up or scale out
  - O Consider implementing a Joget Server Clustering using the Joget Large Enterprise Edition (LEE) in a clustered environment for scalability and redundancy.
